FLE TRIBE

WEEK 10 · THURSDAY · LESSON GUIDE

Undoing mistakes & .gitignore

This week: Use the terminal confidently and track every change to your code with Git.

Undo, safely

- `git restore file.js` : throw away changes you haven't committed.
- `git restore --staged file.js` : unstage a file but keep your changes.
- `git commit --amend` : fix the last commit's message or add a forgotten file (before you push).
- `git revert <commit>` : make a new commit that undoes an old one. Safe even after pushing.

Keep things out of Git

Create a `.gitignore` file:

```
node_modules/
dist/
.env
.DS_Store
```

Never commit passwords, API keys or `.env` files. Once something is pushed, assume it's public forever.

Good commit messages

Say what the commit does, in the present tense: **"Add dark mode toggle"**, not "stuff" or "fixed". One commit = one change.

Research questions

Answer these in the app, in your own words, to unlock the next lesson.

1. What should never be committed to Git?
2. Undo a commit with `git revert` and explain what happened.
